ABSTRACT

RAPLOT II is a computer program for processing radiation and navigation data from field surveys of the Radioisotopic Sand Tracer (RIST) study, but is applicable to any survey type operation on the nearshore Continental Shelf. Collected data are punched onto paper tape by the data collection computer on the research vessel. The data are later transferred to magnetic tape which provides the input for the RAPLOT II Program. Program control parameters are on punched cards. The navigation data, which consists of ranges to two shore-based radar beacons, are first edited for spurious data, and then converted to rectangular coordinates (in this case the California Lambert Coordinate System). Radiation data are converted to count rate as counts per second. Background count rate is computed and subtracted from the observed count rate, and any radiation counts that are significantly above the background count rate are corrected for time of decay since the isotope was injected. Output from the program is in three forms - printed output, graphical output, and magnetic tape record. The processed data are transferred to magnetic tape and made available for further processing such as the generation of contour maps.

FOREWORD

CERC Miscellaneous Paper 2-69, Radioisotopic Sand Tracer Study, Point Conception, California, reported the early results of the RIST study. This study is part of Contract AT(49-11)-2988 between the Atomic Energy Commission and CERC. Other participants in this continuing multi-agency study are the Oak Ridge National Laboratories of the Atomic Energy Commission; U. S. Navy Pacific Missile Range; U. S. Air Force (Western Test Range, First Strategic Aerospace Division); U. S. Army Corps of Engineers Los Angeles District office; NASA (Nuclear Systems and Space Power Division), the State of California (Department of Water Resources) and U. S. Army Mobility Equipment Command. The study involves the collection and analysis of an enormous amount of data. Computer processing is the only means by which these data could be handled.

Philip A. Turner, a geologist, developed the original RAPLOT program and prepared this report. The work was done under the general supervision of David B. Duane, Chief, Geology Branch, and George M. Watts, Chief, Engineering Development Division. CERC continues to refine data processing and improve the printed and graphic output which consists of maps drawn by an incremental plotter.

At the time of publication, Lieutenant Colonel Edward M. Willis was the Director of CERC; Joseph M. Caldwell was Technical Director.

NOTE: Comments on this publication are invited. Discussion will be published in the next issue of the CERC Bulletin.

This report is published under authority of Public Law 166, 79th Congress, approved July 31, 1945, as supplemented by Public Law 172, 88th Congress, approved November 7, 1963.

Section A. INTRODUCTION

In 1966 the Coastal Engineering Research Center (CERC), in cooperation with the Atomic Energy Commission, initiated a 3-year radioisotopic sand tracer study of littoral transport around Point Conception, California. The purpose was to develop and use radioactive tracers for research in sand movement and littoral processes. The objectives included determination of suitable radioactive isotopes, development of handling and survey procedures, and development of computer programs for editing, processing and graphical display of the data. At the same time, studies of sediment transport around the Point Conception headland and of the mechanics of littoral transport were conducted. Methods developed by this program have direct application to engineering design of harbor development and beach erosion prevention, and quasi-military application such as the location of radioactive and other toxic materials.

Sand grains indigenous to the study area are labeled with a radioisotope that does not adversely affect their hydraulic properties. A mobile detector system, using cesium iodide crystals and housed in a "ball" towed behind an amphibious vehicle, detects the location and intensity of the radiation. Concurrently, additional field data are collected on sediment size and composition, isotope distribution, beach and nearshore bottom topography, weather, and sea and swell conditions.

During a sand-tracer field investigation, radiation measurements are made continuously as the mobile detector system is towed along a beach, through the surf, and over the offshore bottom. With a time selection mode for data acquisition available in increments from 0.1 to 10.0 seconds, a large mass of data is accumulated in a few hours. During a field test, surveying may go on several hours a day for several weeks. Computer processing is necessary to study and evaluate the great volume of collected data. Plotting and posting of the survey data is also useful for monitoring field operation.

The initial field investigations at Surf, California, relied on manual preparation of maps and subjective interpretation of data printed by the teletype of the onboard data acquisition system. It immediately became evident that computer processing and plotting must be employed in future operations, and CERC undertook development of computer programs to generate plots useful to continuing field operations. This specific program is called RAPLOT. The first version of the program was used to process the data collected in the December 1967 field test at Point Conception, California, and is documented in Appendix D of CERC report, M.P. 2-69, by Duane and Judge (1969). RAPLOT was originally compiled and made operational on the UNIVAC 1108 at the National Bureau of Standards, with graphic display on a Benson-Lehner incremental plotter at CERC. Later, the program was adapted to the IBM 7094 Computer and Milgo plotter at the Western Test Range of Vandenberg Air Force Base. This version of the program was used to support later field tests at Point Conception and Surf, California, in September and October 1968 and in February and June 1969.

Improvement and modification of program data acquisition systems created changes in the collection format which required a new version of the RAPLOT program. At the same time, experience gained from running the RAPLOT program was incorporated to provide an improved and more sophisticated data processing capability for the RIST project. The new program is called RAPLOT II and was used at CERC for processing field data for all tests after December 1968. Subsequently, the program was modified to run on an IBM 7094 computer to produce plots on a Stromberg-Carlson 4020 cathode ray tube. This version is called RAPLOT III (See Appendix B, page 47).

Section B. SUMMARY OF RAPLOT II PROGRAM

1. Hardware Requirements

RAPLOT II was written in FORTRAN V for the UNIVAC 1108 Computer and EXEC II operating system at the National Bureau of Standards (NBS) in Gaithersburg, Maryland. CERC is connected to NBS by a leased telephone line and has a UNIVAC 1004 for its remote terminal. The NBS UNIVAC 1108 has 65,000 words of core memory of which 38,400 are required for the RAPLOT II Program. FORTRAN V employs advanced features not found in standard FORTRAN IV. They are the NTRAN subroutine for executing binary input-output commands, and the FLD function, a bit manipulation routine.

For field program use, RAPLOT II has been modified and written in FORTRAN IV to run on an IBM 7094 computer at the Pacific Missile Range data processing center at Point Mugu, California. The size of the program had to be reduced considerably to fit into the 32,000 word memory. Consequently, the processing of the data is less thorough, and the writing out of the processed data on magnetic tape was eliminated. This version was used to support a RIST field test near Point Mugu where the primary requirement was for quick printout and graphic display of the processed survey data.

2. Program Description and Logic

A flow chart of the program is given in Figure 1; an outline description of the main steps in the program follows:

a. Read in two program control cards and a file legend card. Additional control parameters are computed from these input parameters.

b. Read in from magnetic tape a data file from a radioisotopic tracer survey.

c. Check radar beacon ranges for errors. If distance-time ratio for successive ranges indicates a ship speed greater than 6 knots, or 3.09 meters per second, correct the ranges by linear interpolation. Experience has indicated that these beacon ranges may be erroneous (as much as an order of magnitude) as often as 5 percent of the time.

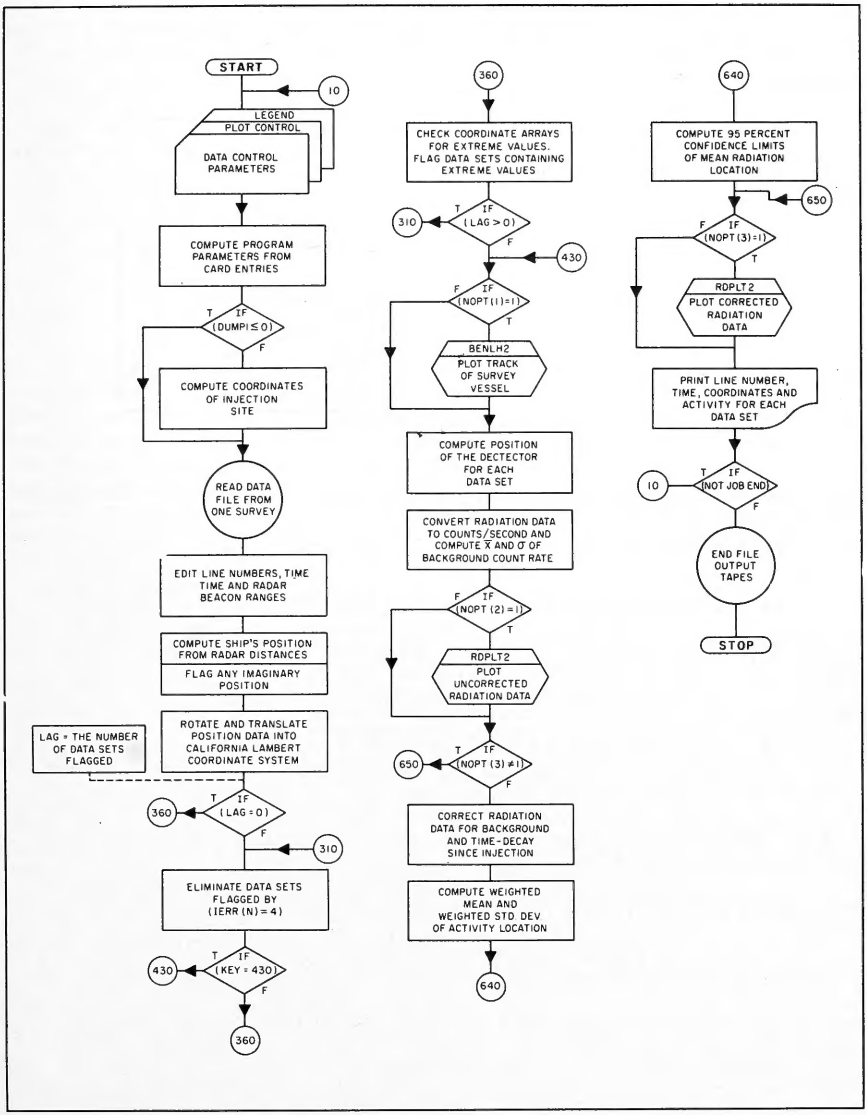

Figure 1. Flow Chart of RAPLOT II Program

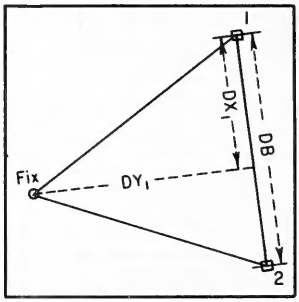
d. Compute the position of the survey vessel at each fix. The program control cards provide the California Lambert Coordinates of the shore beacon, and the data input tapes provide the beacon ranges. By the cosine law this can be translated into distance in terms of a rectangular coordinate system:

$$DX_1 = (DB^2 + D_1^2 - D_2^2)/(2 \cdot DB)$$

$$DY_1 = (D_1^2 - DX_1^2)^{\frac{1}{2}}$$



Where D_1 = the distance of survey vessel from the upcoast radar beacon

D_2 = the distance from the downcoast beacon

DB = the distance between the two beacons

DX_1 = the distance of the fix position of survey vessel from the upcoast beacon in a direction parallel to a line intersecting the two beacons

DY_1 = the distance of the fix from an upcoast beacon in a direction normal to a line intersecting the two beacons.

These distances may be translated and rotated to give the Lambert Coordinates for each fix

$$NORTH_f = DX_1 \sin\theta + DY_1 \cos\theta + NORTH_b$$

$$EAST_f = DX_1 \cos\theta - DY_1 \sin\theta + EAST_b$$

Where θ = the angle of rotation of the coordinate system

$NORTH_b$ and $EAST_b$ = the Lambert coordinates of the upcoast radar beacon

$NORTH_f$ and $EAST_f$ = the coordinates of the fix.

Occasionally the two radar beacon ranges will produce an imaginary position. When this occurs, one of the coordinates of the radar fix is defined by the square root of a negative number. When such an imaginary fix occurs, the line of data producing the imaginary fix is eliminated from the file being processed.

e. The north and east coordinate arrays are searched for extreme values by Chauvenet's criterion and any data set containing extreme values is eliminated. Chauvenet's criterion is based on the normal distribution, and a value is rejected if the probability of occurrence of such a deviation from the mean of the n measurements is less than 1/2 n (P. R. Rider, 1933).

f. Plot the track of the survey vessel by a call to subroutine BENLH2.

g. Compute the position of the mobile underwater detector for each fix by correcting for the distance the detector is towed astern of the survey vessel. Cable length, mean water depth, and length of survey vessel, are all input on the program control card. Assuming a position for the detector vehicle at the beginning of the survey, the position of the detector for each fix is computed by linear interpolation from the present position of the vessel to the last interpolated position of the detector.

$$YD_n = YV_n - \frac{CABLE\ (YV_n - YD_{n-1})}{\sqrt{(YV_n - YD_{n-1})^2 + (XV_n - XD_{n-1})^2}}$$

$$XD_n = XV_n - \frac{CABLE\ (YV_n - YD_{n-1})}{\sqrt{(YV_n - YD_{n-1})^2 + (XV_n - XD_{n-1})^2}}$$

where XD and YD are the coordinates of the detector and XV and YV are coordinates of the vessel. CABLE is the horizontal distance from the detector to the survey vessel.

h. Radiation data are converted to counts per second, and the mean and standard deviation of the background count rate is computed. An estimated background count rate is entered on the data control card for each channel. This estimated background count rate is used to compute the extreme values of the range of the background radiation level, again by means of Chauvenet's criterion. All counts between these extreme ranges are averaged to obtain the mean background count rate for each channel.

i. Plot uncorrected radiation values by a call to BENLH2 through RDPLT2 entry.

j. Correct the radiation data by subtracting the mean background count rate. Then correct the remainder, if it is significantly higher than background, for the time of the decay since the isotope was injected.

$$CCR = (NCR - 3\sigma)e^{\Lambda t} + 3\sigma$$

where $$\Lambda = \frac{\log_e(2)}{T_{\frac{1}{2}}} \quad , \quad \text{and}$$

where CCR = the corrected count rate

NCR = the net (observed radiation value less mean background) count rate

σ = the standard deviation of the background count rate

$\underline{t}$ = the elapsed time from the injection to the time of the fix

$T_{\frac{1}{2}}$ = the isotope halflife in hours.

Only radiation count rates that are significantly greater than background are corrected for time of decay. Otherwise, in a survey made one or more halflives after the injection, the correction would inflate background radiation readings to such a degree that they would appear to be significant.

k. Compute the weighted mean and weighted standard deviation of the coordinate location of the radioactivity. Compute the 95 percent confidence limits of the mean radiation location.

$$\overline{XD} = \frac{\sum_{i=1}^{n} XD_i \cdot CCR_i}{\sum_{i=1}^{n} CCR_i}$$

$$\overline{YD} = \frac{\sum_{i=1}^{n} YD_i \cdot CCR_i}{\sum_{i=1}^{n} CCR_i}$$

l. Print out the sequence number, time, radar beacon ranges, coordinates, and activity for each line of data.

m. Return to the beginning of the program to read in more data control cards, and process another file of data unless it is the end of job, in which case processing ends.

Section C. SUBROUTINES USED IN THE PROGRAM

1. BENLH2 - Plotting Subroutine

Subroutine BENLH2 performs the operations necessary to produce a plot of the trackline and of the radiation data on the Benson-Lehner incremental plotter. BENLH2 does this by calling the several subroutines of the Benson-Lehner plot package which translates the data given to the subroutines by BENLH2 into plot commands that are written out onto magnetic tape. The tape is used to drive a Benson-Lehner model 305 incremental plotter off-line. Figure 2 is a flow chart of this subroutine.

Subroutine TRACK is substituted for subroutine BENLH2 to produce the RAPLOT III program. TRACK interfaces the RAPLOT program with the plot subroutines for the Stromberg-Carlson 4060 cathode ray tube. Otherwise, it functions essentially like subroutine BENLH2. Both subroutines plot the trackline followed by the survey vessel, and both will also plot the uncorrected or corrected radiation values for each survey. These are symbol plots in which the count rate is represented by a symbol indicating a value between arbitrarily fixed limits. For uncorrected radiation, the limits are established in terms of standard deviation from the mean background count rate. For corrected radiation count rate, the internal limits for each symbol are established on a power of 2 scale. Also, a special symbol is used to indicate background if the count rate is less than 3 standard deviations from the background count rate. If the count rate is more than 3 standard deviations below background, the value is not plotted at all. The reason for this is that an abnormally low count rate may indicate that the detector was "flying" meaning that it was not in contact with the ocean bottom at the time of the fix. Both BENLH2 and TRACK will plot the location of the mean radiation position referred to as RADBAR. They may also plot the location of the injection site, if this is desired.

2. Statistical Subroutines

The subroutines described below are used to perform certain statistical computations required by the RAPLOT II program. To reduce the time necessary to prepare the program, these subroutines were taken from the STAT-PACK, a library of statistical subroutines available on the UNIVAC 1108 system. Further details may be obtained from the STAT-PACK Programmers' Reference Manual.

Subroutine STDEV computes the standard deviation of an array by the following formula:

$$\sigma = \left(\frac{\sum_{i=1}^{n} (X_i - \bar{X})^2}{n} \right)^{1/2}$$

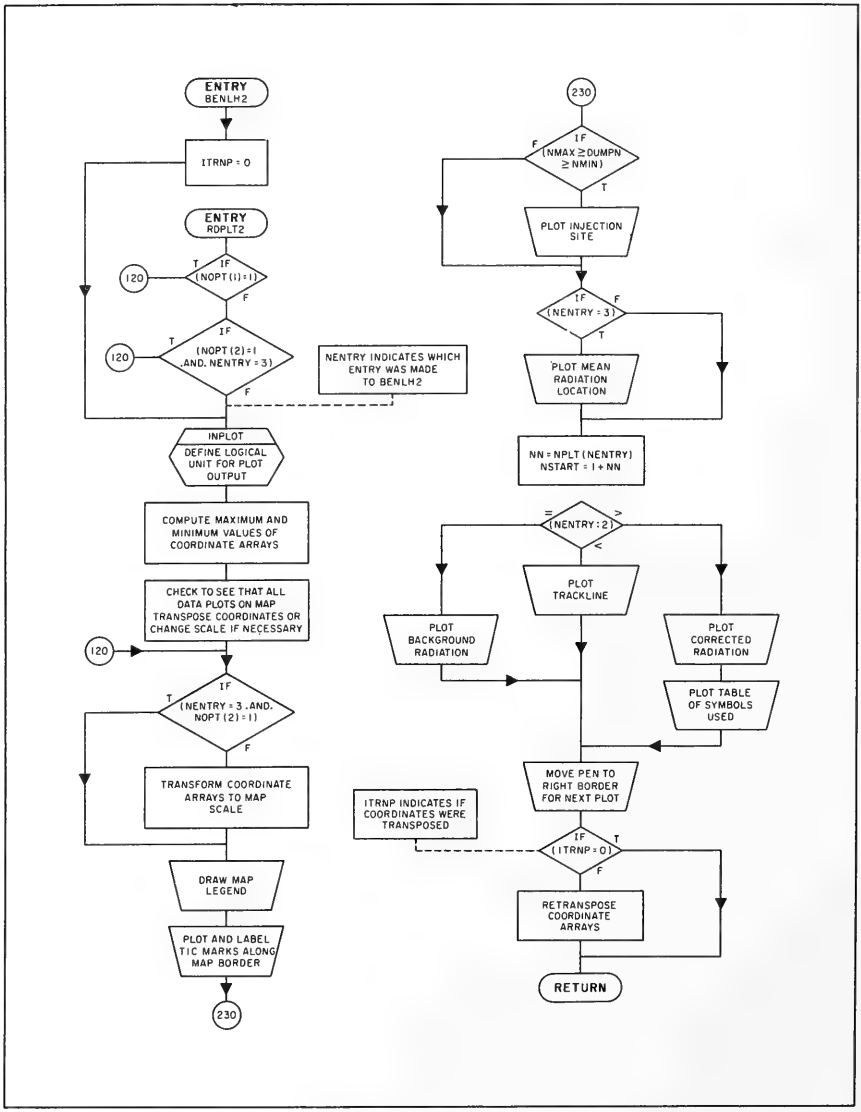


Figure 2. Flow Chart of BENLH2 Program

where X = the array of values

$\overline{X}$ = the arithmetic mean of the X array

n = the number of elements in the X array

σ = the standard deviation

Subroutine AMEAN is called to compute the arithmetic mean of the X array.

Subroutine TINORM computes the value of the inverse of the normal distribution by a rational approximation. The inverse normal distribution is defined by the solution for X of the following integral equation

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{X} e^{-t^2/2} \, dt = \alpha$$

where α is the probability for which the ordinate is to be calculated. The rational approximation itself may be ascertained from the FORTRAN statements in the subroutine.

3. Input-Output Subroutines

The binary input-output statements in FORTRAN, although convenient to use, cannot make efficient use of magnetic tapes because the language does not permit total parallel processing. Furthermore, a considerable amount of time is used in processing a list because of its generality. More efficient use is attained by buffering the input or output in parallel with computing. On the UNIVAC 1108 system the NTRAN subroutine provides a means of buffering through a call statement in FORTRAN:

CALL NTRAN (UNIT, sequence of operations)

in which UNIT is an integer constant or variable designating the logical unit. If the unit is not busy, NTRAN initiates the first operation and stacks the remainder in a waiting list. If the unit is already busy, then the entire sequence is stacked in a waiting list and chained to the previously stacked sequence. Control is then returned to the program following the call NTRAN statement. When an interrupt occurs, NTRAN records the transmission status, initiates the next operation in the chain and returns control to the interrupted program.

The NTRAN subroutine is used to write out on magnetic tape the arrays containing the legend, sequence number, underwater detector coordinates and corrected count rate for both radiation channels for each file of survey data being processed. The information thus stored on

magnetic tape may be used for further processing such as drawing contour maps. No provision is made for outputting the processed data in RAPLOT III because no further processing was planned for any of the field test sites. Also deletion of the output statements reduces the running time of the program.

Call NTRAN statements are also used in RAPLOT II to position the input tape by end of file marks.

Section D. PROGRAM INPUT

1. Card Input

Input for the RAPLOT II program comes from punched cards and from magnetic tape. Three program control cards are read in for each file of survey data processed. Formats, and descriptions of the variables written onto the cards are given in Table I; names given to the variables in this table are the ones employed by the program. Figure 3 shows a data sheet that is used for filling out the control cards. It is useful not only for filling in the parameters on the cards, but also for keeping track of the data files when large numbers of files are being processed.

The last 12 characters of the legend (Card 3, spaces 66-78) are used for file identification. Before a file of survey data is read in, a 7-word identification array called SENTNL is read in from the beginning of the tape file. The first two words in SENTNL are compared with the last two words in LEGEND. If a match is not found, the tape is positioned at the beginning of the next file and a new SENTNL array is read in. This procedure is in lines 48 through 52 of the source language listing of RAPLOT II in Appendix A. It has been deleted from RAPLOT III.

2. Tape Input

When a RIST survey is underway in the field, data from various sensors are assembled by the onboard detector system, and punched on 8-channel paper tape in American Standard Code for Information Interchange (ASCII) code. At present, there are seven data fields for each line of record. A brief description of the variables and the tape record format is given in Table II; Figure 4 is a sample listing from a paper-tape data file.

In the actual processing of the RIST data files, it has been found necessary to edit the data files prior to putting them through the RAPLOT II program. The edited data are written out in unformatted magnetic tape files. This is why the READ statement in line 58 of the listing in Appendix A is an unformatted FORTRAN READ statement. Unformatted (or binary) input-output statements are much more efficient for the computer to execute than formatted statements. For that reason, they are employed wherever possible. RAPLOT III employs a formatted READ statement (line 51, Appendix B) for inputting a data file, since the need for short turn-around time is greater than the need to edit data files when supporting a field test.

TABLE I

Format of Program Control Cards

I Data Control Card (3F3.0,2F7.0,1X,2F2.0,F3.0,F5.2,3F2.0,4(1X,F7.0),I3)

Column	Variable	Description
1-3	CABLE	Length of cable, in feet, on which the detector is towed.
4-6	DEPTH	Average water depth plus freeboard, in feet.
7-9	BOAT	Distance from radar mast to cable stanchion in feet.
10-16	BKG(1)	Estimated background count rate (counts per second) for radiation channel 1.
17-23	BKG(2)	Same for radiation channel 2.
25-28	ZHR,ZMIN	The time of injection in hours and minutes (24-hour clock).
29-31	DAYS	The number of days that have elapsed since the injection.
32-36	HLIFE	The halflife of the radioisotope in days.
37-40	SETIME, RMIN	The time when the survey was started, in hours and minutes (24-hour clock).
41-42	SEC	The time, in seconds, between successive fixes.
44-50	BEACIN	California Lambert Coordinates of the radar beacons. BEACON 1 is always the upcoast beacon.
52-58	BEACIE	
60-66	BEAC2N	
68-74	BEAC2E	
75-77	ISKIP	The number of lines to skip at the beginning of a data set in order to avoid reading in some bad data.

TABLE I (Continued)

Format of Program Control Cards

II Plot Control Card (4I1,F10.0,1X,3I2,1X,F10.0,2(1X,F10.0),1X,A6)

Column	Variable	Description
1-4	NOPT	Plot option controls. A numeral 1 in the column indicated causes the various options to be executed.
1		Plot trackline followed by survey vessel.
2		Plot uncorrected radiation values.
3		Plot radiation values corrected for background and for decay since injection.
4		Unused.
5-14	SCALE	Map scale in feet per inch.
16-17	NPLT(1)	Options used for spotting data points for each plot option. User can specify that every Nth point be plotted. If left blank, every point will be plotted.
18-19	NPLT(2)	
20-21	NPLT(3)	
23-32	GRID	Intervals on the coordinate grid at which Lambert Coordinates will be posted. If GRID=0, tick marks are not plotted.
34-43	DUMP 1	Distance in meters from the injection site to the upcoast and downcoast beacon, respectively. If the fields are blank, then the injection site is not plotted.
45-54	DUMP 2	
56-61	INDATE	Day, month and year that the radioactive sand was injected.

III Plot legend card (13A6,L2)

1-78	LEGEND	A descriptive legend that is included on the printed output, and is also written on the lower margin of the map.
79-80	JOBEND	The letter 'T' is entered here if the data file being processed is the last one in the job. Otherwise the field is left blank.

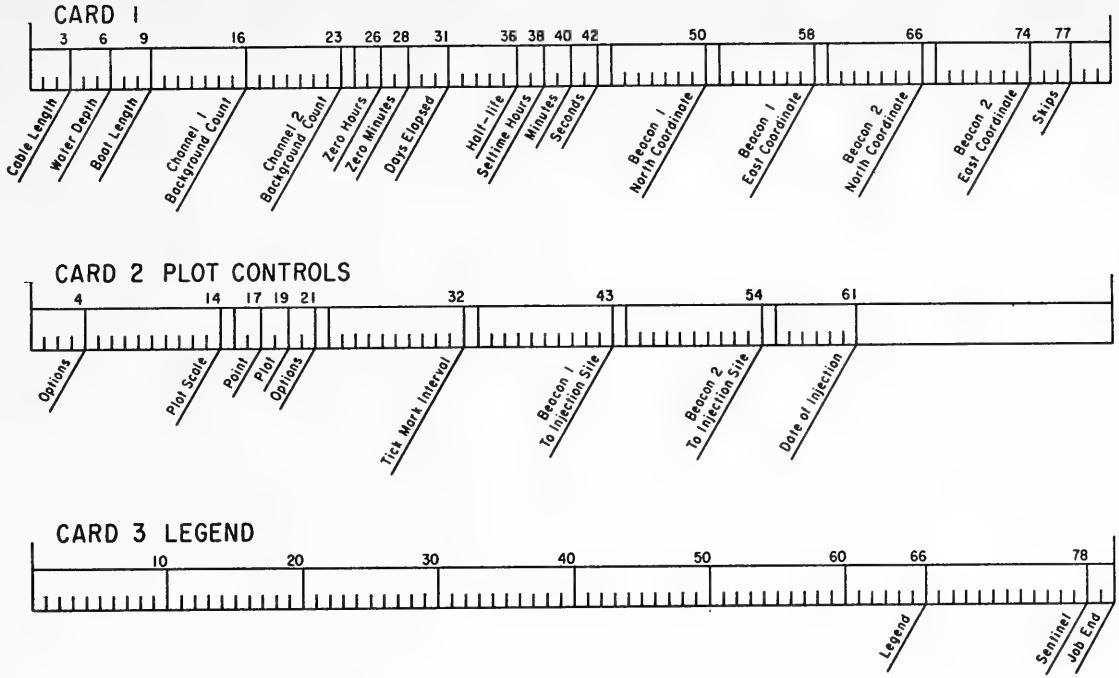

Figure 3. Data Sheet for RAPLOT II Control Cards

TABLE II

Format of Paper-tape Record on Which RIST Survey Data is Collected
Paper-Tape Format (I6,3F7.1,3F7.0)

Column	Array	Description
1-6	NMBR	A line (record) number which is incremented with each line of data unless manually reset.
8-13	TIME	Cumulative time, in tenths of seconds, since the beginning of the survey. Time is reset to zero at the beginning of each survey.
15-20	D_1	Distance, in tenths of meters, from the upcoast radar responder beacon.
22-27	D_2	Distance, in tenths of meters, from the downcoast radar responder beacon.
29-34	RAD_1	Radiation Channel 1: pulses from differential discriminator accumulated for time between successive records. It is automatically reset to zero at the writing of each record.
36-41	RAD_2	Radiation Channel 2: same description.
43-48	FATH	Depth of water recorded by fathometer. This is not presently in operation.

Figure 4. Sample Listing of Input Data File for RAPLOT II

Section E. PROGRAM OUTPUT

1. Printed Output

Three forms of output are generated by the RAPLOT II program - printed output, graphical output, and magnetic tape output.

The printed output for one data file consists of one page listing the program control parameters and summary statistics (Figure 5) followed by a complete listing of the unprocessed and processed data arrays (Figure 6).

The printout of program parameters and summary statistics for RAPLOT III (Figure 7) is virtually the same. However, the radar-range data and uncorrected radiation data are deleted from the printed listing (Figure 8). Also, only one channel of corrected radiation data is included.

Because of the large volume of data files that may be processed by the RAPLOT II program, it is usually necessary to keep track of the number of pages of output. Fifty lines are printed to a page of output; one page is required for program control parameters and another page for summary statistics. Therefore, the number of pages per data file = 2 + (number of lines of data/50.)

2. Graphical Output

Graphical output from RAPLOT II is in the form of plot commands that are either written out on magnetic tape or punched onto cards to be used to drive a Benson-Lehner plotter off-line. Under the present setup, the plot commands are written out on logical tape unit 9; therefore, this same unit cannot be used for other tape input or output without first making changes. On the UNIVAC 1108 system, the plot commands are blocked and written out in card image length records at 556 bits per inch in even parity, BCD. Experience has shown that one full tape will hold approximately 20 separate plots. Assuming that 2 plots are generated per file of data, this means that 10 files of radiation survey data will generate a full tape of plot commands.

RAPLOT II graphical output consists of three types of plots - plots of the trackline followed by the survey vehicle, plots of uncorrected radiation data (for plotting background radiation), and plots of corrected radiation data. Selection of the various plots is controlled by the variable NOPT in Table I. The plot selection options are independent of each other. Any one of the three plot types may be selected, or all three if it is desired. Normally, the trackline plot is selected and then, depending on whether the data is from a background or a radiation survey, either the plot of uncorrected radiation or corrected radiation data is selected. Plots of the survey vehicle trackline and the corrected radiation data are shown in Figures 9 and 10.

Figure 8. Sample of Printed Output of RAPLOT III Processed Data for One RIST Data File

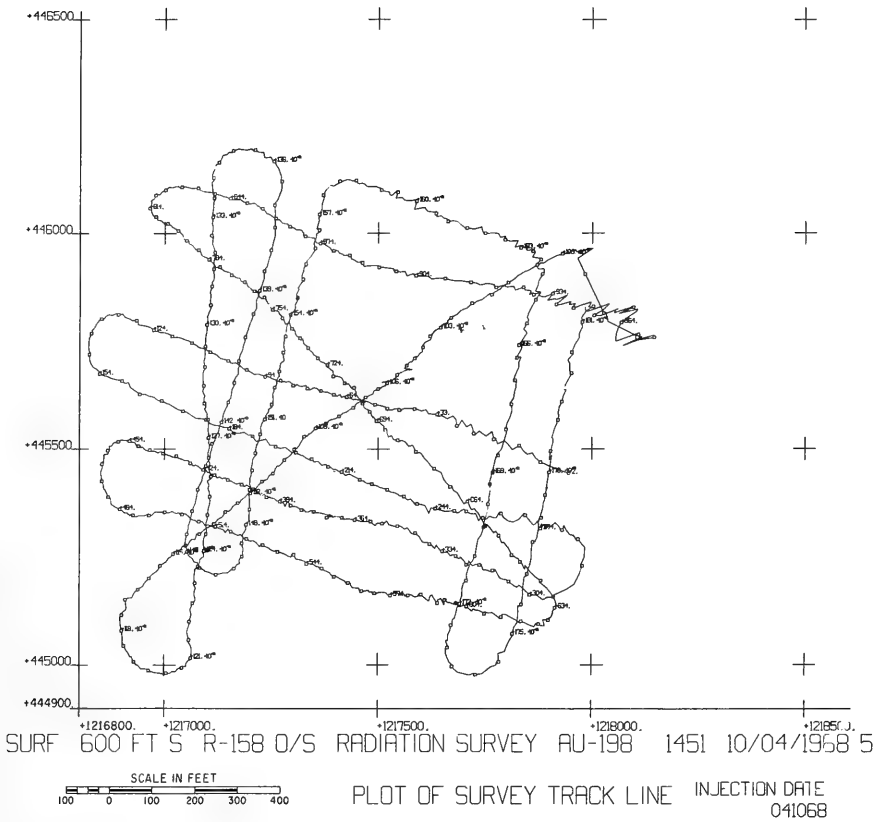

Figure 9. Trackline Plot Produced on Benson-Lehner Plotter by Subroutine BENLH2 of RAPLOT II

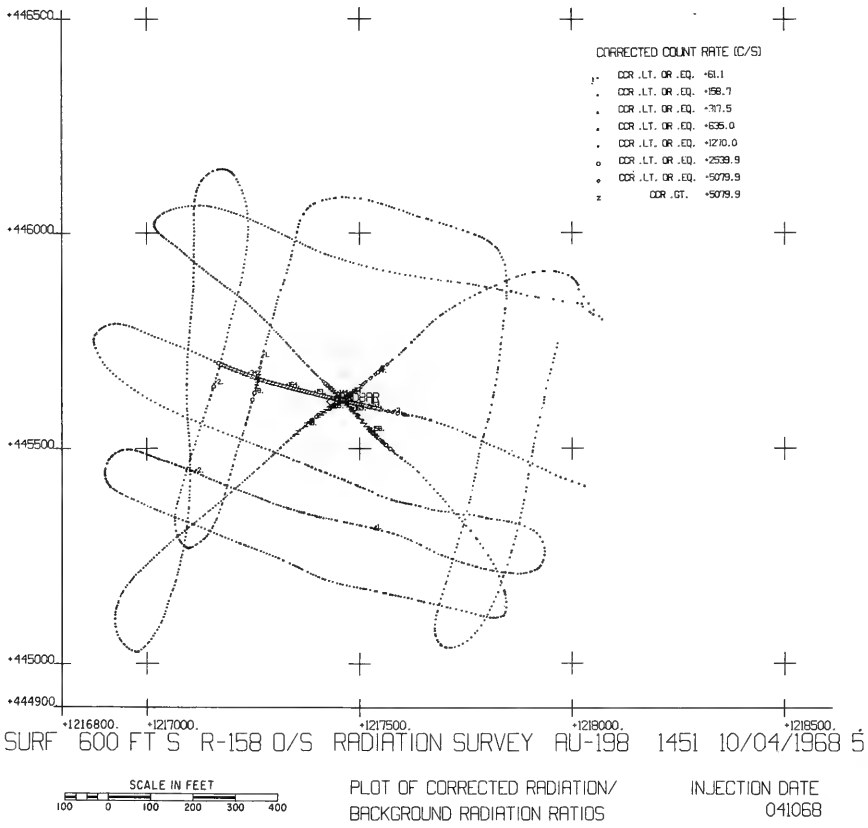

Figure 10. Plot of Corrected Radiation Data Produced on Benson-Lehner Plotter by Subroutine BENLH2 of RAPLOT II

The graphical output from RAPLOT III is produced on the Stromberg-Carlson 4020 computer recorder. The technique for getting the plots is somewhat the same as the Benson-Lehner plotter in that the plot commands are written out on magnetic tape and are then used off-line to generate the plots. There is a highly developed software package that goes with the S-C 4020 and if it is planned to use this method of generating plots, the Programmers' Reference Manual for the S-C 4020 should be used. Figure 11 is a trackline plot produced on the computer recorder at the Pacific Missile Range data processing center at Point Mugu. Figure 12 is a plot of uncorrected radiation data that was also produced there.

3. Magnetic Tape Output

The processed data is stored on magnetic tape for future reference by the calls to the NTRAN subroutine. The arrays written out are: LEGEND, sequence number (NMBR), coordinates of radiation location (NCORD and ECORD), and corrected radiation data (CCR). This procedure has been eliminated from RAPLOT III.

Section F. INSTRUCTIONS FOR RUNNING PROGRAM

An example of a job deck setup for running RAPLOT II is shown in Figure 13. Further instructions on running jobs are in the 1108 EXEC II Programmers' Reference Manual. Running time depends on the number of files being processed and the number of records in each file. Figure 14 shows a graph of UNIVAC 1108 central processing unit time to process one file versus the number of records in the file.

For running version III on the IBM 7094, consult the IBM reference manuals for FORTRAN IV and the system monitor (IBSYS). It may also be useful to have a copy of the Programmers' Reference Manual for the S-C 4020 Computer Recorder.

Section G. RADIATION CONTOURING PROGRAM

Present programming effort is directed toward completing RADCON, a FORTRAN V program for drawing contour maps of radiation data. The input for this program will be the files of processed data on magnetic tape that have been generated by RAPLOT II. If necessary, two or more data files may be combined to provide the input for one contour map. The radiation data are first smoothed by a moving average (LINAVE) procedure and then interpolated over a uniform grid by a weighted least-squares numerical approximation (NUPRX). The resulting grid is then contoured at equally spaced intervals of the gridded values. There are also options for transforming the radiation data, although the number of options and types of transformation is still undecided.

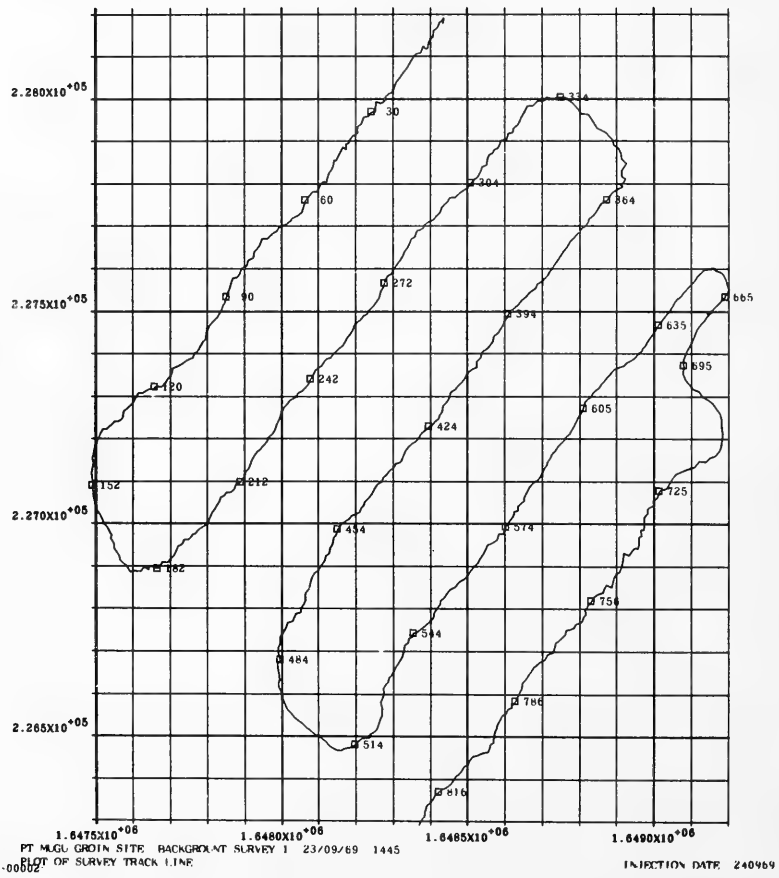

Figure 11. Trackline Plot Produced on S-C 4060 Computer Recorder by Subroutine TRACK of RAPLOT III

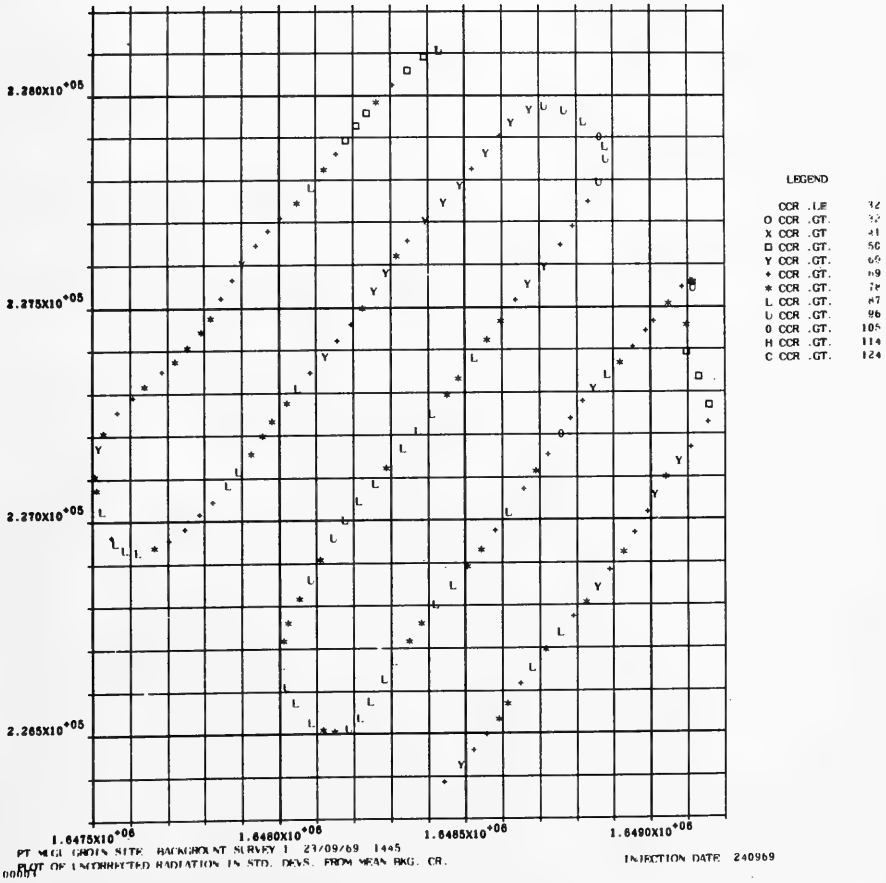

Figure 12. Plot of Uncorrected Radiation Data Produced on S-C 4060 Computer Records by Subroutine TRACK of RAPLOT III

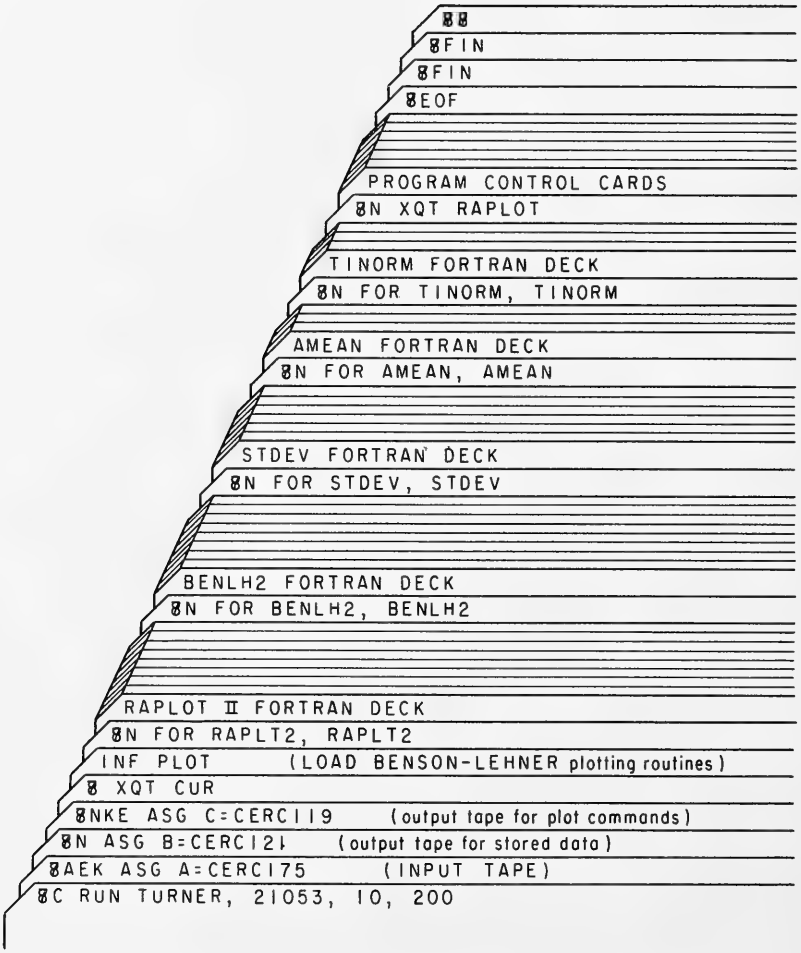

Figure 13. Example of a RAPLOT II Job Deck Setup for UNIVAC 1108 Running under EXEC II

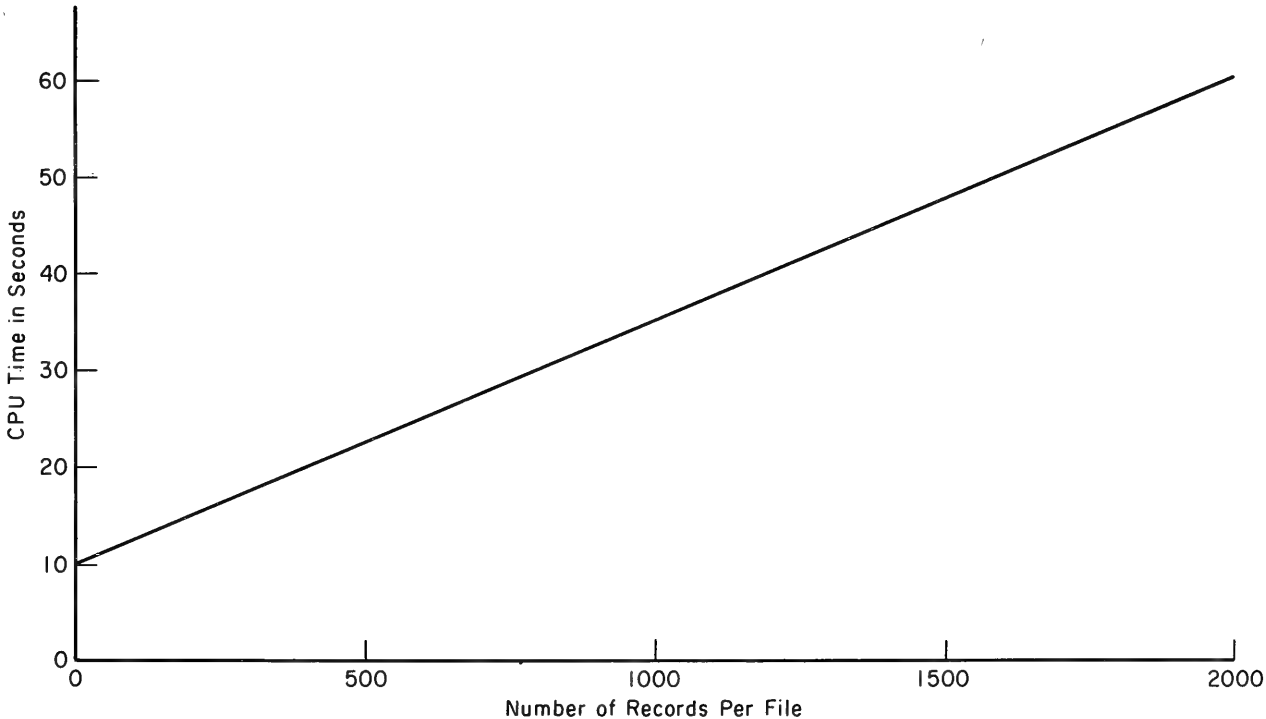

Figure 14. Graph of CPU Time Required to Plot One Data File Versus the Number of Records in the File.

APPENDIX A

LISTING AND INDEX OF RAPLOT II PROGRAM

The source deck has been analyzed routine-by-routine and a directory of all statement numbers and variable names used in the source deck. The symbols are listed numerically and alphabetically. Beside each symbol appears line numbers followed by a code which designates where and how the symbol was referenced. The codes used are as follows:

Code	Meaning
Blank	A simple reference, such as the use of a statement number in an IF statement or a variable used in an arithmetic statement.
=	Arithmetic definition of a variable which appears on the left of an = sign.
*	Statement number defined at this line.
AG	Variable appears as an argument in a subroutine or function statement or as an argument in a CALL statement.
CO	Variable appears in a COMMON statement.
CX	Variable appears in a COMPLEX statement.
DA	Variable appears in a DATA statement.
DB	Variable appears in a DOUBLE PRECISION statement.
DI	Variable appears in a DIMENSION statement.
EQ	Variable appears in an EQUIVALENCE statement.
EX	Function name appears in an EXTERNAL statement.
IN	Variable appears in an INTEGER statement.
LG	Variable appears in a LOGICAL statement.
NM	Variable appears in a NAMELIST statement.
PR	Variable or FORMAT number appears in a PRINT statement.
PU	Variable or FORMAT number appears in a PUNCH statement.
RD	Variable or FORMAT number appears in a READ statement.
RL	Variable appears in a REAL statement.
WR	Variable or FORMAT number appears in a WRITE statement.

13. ABSTRACT

RAPLOT II is a computer program for processing radiation and navigation data from field surveys of radioisotopic sand tracer (RIST) study, but is applicable to any survey type operation on the nearshore Continental Shelf. Collected data are punched onto paper tape by the data collection computer on the research vessel. The data are later transferred to magnetic tape which provides the input for the RAPLOT II Program. Program control parameters are on punched cards. The navigation data, which consists of ranges to two shore-based radar beacons, are first edited for spurious data, and then converted to rectangular coordinates (in this case the California Lambert Coordinate System). Radiation data are converted to count rate as counts per second. Background count rate is computed and subtracted from the observed count rate, and any radiation counts that are significantly above the background count rate are corrected for time of decay since the isotope was injected.

Output from the program is in three forms - printed output, graphical output, and magnetic tape record. The processed data are transferred to magnetic tape and made available for further processing, such as the generation of contour maps.

DD FORM 1 NOV 68 1473 REPLACES DD FORM 1473, 1 JAN 64, WHICH IS OBSOLETE FOR ARMY USE.
